1.0 SUMMARY

This is the final report of the work performed under contract to NASA Manned Space Flight Center on the design and test of an all mechanical Mass Flow Controller. The program involved design, development, manufacture of four MFC units and a test program using inert gas as the test medium. The unit controlled the pressure within ± 1 percent. An analytical method is described for relating the control pressure error with error in mass flow.

2.0 INTRODUCTION

Control of the mass flow rate is essential for controlling the fuel-oxidizer mixture ratio or controlling the thrust level of a rocket engine. In a rocket engine designed for a constant thrust level, the flow rate of the propellants must be maintained essentially constant. When gaseous propellants are used, it becomes more difficult to maintain a constant flow rate than when liquid propellants are used. In a typical rocket engine system using gaseous propellants, both the pressure and temperature of the propellant supply will vary. The function of a mass flow controller is to compensate for these variations as required to maintain the flow rate constant.

An all mechanical approach to mass flow control is illustrated in Figure 1. In this approach a fixed flow restriction is combined with a temperature biased absolute pressure regulator. The pressure regulator maintains a constant control pressure, Po, so long as the temperature of the propellant does not change, even though the propellant inlet pressure varies. Under these conditions the pressure at both ends of the fixed flow restriction is constant and the flow rate is therefore constant. When the propellant temperature changes, the temperature biased pressure regulator alters the control pressure proportionally so as to maintain the flow rate constant through the fixed restriction.

The equation for subsonic gas flow through a fixed restriction can be approximated by the equation

It can be seen that the flow rate through the fixed restriction will be constant if the term under the radical is maintained constant. This term is constant when the pressure drop, Po - Pc, is caused to vary with the absolute temperature, T. This is easily seen when Pc and Z are constant; actually these two terms vary somewhat with temperature, which requires minor modification to the proportionality maintained between Po - Pc and T.

3.0 BASIC DESIGN CONCEPT

In the all mechanical approach a fixed flow restriction is combined with a temperature biased absolute pressure regulator, hereinafter referred to as the Mass Flow Controller (MFC). In a rocket engine the injector together with the ducting connecting the injector and the MFC constitute the fixed flow restriction. At the beginning of the program this flow restriction was assumed to result in a 60 psi pressure drop when passing rated flow at 100°F to a combustion chamber at 300 psia. The chamber pressure varies somewhat with the temperature of the entering propellant in accordance with Figure 2.

Figure 2 was obtained from the expression

$$\frac{Pc(T)}{Pc(560)} = \frac{I sp(T)}{I sp(560)} \qquad (2)$$

which is valid for constant mass flow of the rocket engine.

The variation of specific impulse with temperature was obtained from Figure 3. Figure 3 was prepared from data from NASA Houston for a rocket engine with a O/F ratio of 4, expansion ratio of 40 and a thrust chamber pressure of 300 psia. This curve is valid for O/F ratio from 3.8 to 4.2.

Figure 4 includes two curves, one for oxygen gas and one for hydrogen gas, showing the required variation in control pressure with temperature for constant mass flow. The curves were prepared using the equation

Which is a more exact equation than (1) for the flow through a fixed restriction.

Figure 5 is a schematic drawing of the Mass Flow Controller. It incorporates a shutoff poppet, which is controlled by a two-position, three-way solenoid pilot valve for the off-on function. Downstream of the shutoff poppet is the pressure balanced throttling element, consisting of a stationary cylinder and a rotating cage. The cage is normally positioned by the belleville spring so that its slots are aligned with the slots in the cylinder. When the pressure at the outlet, Po, rises to the set value, the bellows, which connects with the cage through a linkage, rotates the cage toward a more restrictive position. The amount of cage rotation is that required to maintain the outlet pressure at its correct value for the temperature of the propellant. When the propellant temperature increases, the internal pressure in the bellows increases and causes the MFC to control the outlet pressure to a higher value.

1	NO	EER5716	068	BY	WT	PAGE	6
	REV LTR	NC	·				
	DATE	1-19-72					

In order for the MFC to vary the outlet pressure with temperature in accordance with one of the curves of Figure 4, the slope must be correct and the pressure level must be correct. The slope of the curve is determined primarily by the bellows charge pressure: the greater the charge pressure, the steeper the slope (larger pressure change for a given change in propellant temperature). The pressure level of the MFC is determined by the pressure charge and the belleville spring load.

3.1 Tolerance

The all mechanical MFC is basically a temperature biased absolute pressure regulator. It uses a helium charged bellows to sense both the pressure and the temperature of the flowing gas. Because the MFC is a pressure operated device its precision is best expressed in terms of a tolerance in the control pressure, e.g. ±3 psi at 0°F temperature. It is of interest however to relate pressure tolerance to tolerance in mass flow, mixture ratio and thrust when two controllers (an oxygen MFC and a hydrogen MFC) are used to supply a rocket engine.

When one MFC delivers its propellant at a higher or lower pressure than the correct value, it causes a proportional error in the flow rate of its propellant. This error in flow rate results in a deviation in the chamber pressure of the rocket engine. The change in chamber pressure represents a change in the outlet pressure of the fixed flow restriction of the other propellant; consequently it causes an error in the mass flow rate of the other propellant even when the MFC for that propellant is controlling without a pressure error.

An analytical method was developed for relating these tolerances. It consists of assuming a percentage error in flow rate of each propellant and calculating the resulting mixture ratio, chamber pressure, and control pressure for each propellant. Figures 6 and 7 were constructed from the results of several such computations. Details of the method are described below.

An error of +x% error in oxygen flow rate and +y% error in hydrogen flow rate results in the following O/F mixture ratio

O/F =
$$\frac{4(1 + \frac{x}{100})}{1 + \frac{y}{100}}$$
(4)

and a change in flow rate through the engine of

1	NO	EER5716068	BY	PAGE
	REV LTR	NC		
	DATE	1-19-72		

A new chamber pressure was calculated using the chamber pressure from Figure 2 and modifying it by the new mass flow

$$Pc = 1 + \frac{\Delta \omega}{\omega} \qquad x \qquad Pc \text{ (from curve)}$$

Equation (1) was then used to calculate a new outlet pressure, Po, for each propellant. These two pressures were used to establish a point on one curve of Figure 6 or Figure 7.

For an oxidizer-fuel ratio of four, the hardware required for an oxygen MFC should be the same size as a hydrogen MFC. This follows since for equal pressure drop the flow passages should be approximately the same for both propellants. It is therefore logical to expect equal pressure errors of the MFC for each propellant. Figures 6 and 7 show that for equal pressure errors the hydrogen MFC will suffer approximately twice the mass flow percentage error of the oxygen MFC.

Figure 8 is a plot of the allowable pressure band over the entire temperature range band on a mass flowerror of 2-1/2 percent and 5 percent for the oxygen and hydrogen units respectively. This figure shows that the allowable pressure error decreases as the temperature of the propellants decreases.

The allowable pressure control band can be increased without increasing the mass flow error by designing the system for a greater pressure drop through the fixed flow restriction. (See paragraph 6.3)

3.2 Bellows Charge

The bellows is charged with helium gas and subsequently sealed. The charge required to cause the MFC to control the outlet pressure in accordance with Figure 3 may be calculated from a force balance. The force balance, in its simplest form, consists of the

- 1) spring force, F: belleville spring load plus the installed load in the bellows (the bellow is assembled so that it is in compression throughout its stroke). The spring force acts to hold the throttling element in its open position. This force is a function of temperature, decreasing approximately 2% per 100°F increase.
- 2) gas charge, P_b , acting over the effective areas of the bellows, A_b , pushes the throttling element toward the open position. This force varies directly with absolute temperature.

l	NO	EER 5716068	вү	WT	PAGE	8
	REV LTR	NC				
	DATE	1-19-72				

3) outlet pressure, Po, acting over the effective area of the bellows, A_b, opposes the other two forces and balances them, when the outlet pressure reaches the correct pressure value.

The force equation in its simplest form is

If the terms $\frac{F}{Ab}$ and P_b represent their magnitude at 100°F temperature, their magnitude at any lower temperature T

$$\frac{F}{A_b} \qquad (T) \qquad = \qquad \left[1 + .02(560 - T)\right] \times \qquad \frac{F}{A_b} \qquad \dots \qquad (7)$$

The above three equations and the values of Po taken from Figure 3 can be used to calculate P_b and $\frac{F}{A_b}$. These calculations for the oxygen unit give

$$\frac{F}{A_b}$$
 = 248 psi at 100°F

During testing of the prototype MFC it was discovered that the above force balance requires modification in order to account for a temperature dependent closing force. This force results from the pressure drop between the throttling element and the MFC outlet. The pressure drop creates a difference in pressure across the belleville spring, resulting in an additional closing force on the throttling device. Additionally, the pressure drop results in a greater pressure surrounding the bellows than is indicated by the outlet pressure. These two effects are temperature dependent since pressure drop, at constant flow, is temperature dependent.

The effect of the additional closing force was determined empirically. It results in the revised charge pressures and spring loads as follows:

١	NO	EER5716068	BY	PAGE9
	REV LTR	NC		
	DATE	1-19-72		

For the oxygen MFC

$$F/A_b = 246.3 \text{ psi}$$

For the hydrogen MFC

$$P_b = 133.6 \text{ psia at } 100 \text{ °F}$$

$$F/A_b = 261.4 \text{ psi at } 100 \text{°F}$$

3.3 Thermal Response

The thermal response of the MFC is determined by the rate at which the belleville spring and the helium charge inside the bellows respond to a temperature change of the propellant gas. The most rapid change of propellant temperature occurs when the MFC, stabilized at its maximum temperature (100°F), is opened with a gas supply at its minimum temperature (-210°F for an oxygen MFC, -260°F for a hydrogen MFC). In this circumstance the MFC will regulate to a pressure higher than it should until the bellows and belleville cool to near the temperature of the propellant gas. Slower thermal response occurs when oxygen is the propellant as its thermal conductivity is less than that of hydrogen.

Bellows - The bellows thermal response was calculated by assuming that the mass of the bellows is concentrated in the center of the bellows wall and that the length of the conduction path is one-half the wall thickness. The heat transferred from the center of the wall to its outer surface is derived from cooling the bellows mass; i.e.

$$M_bC_b = \frac{dT_b}{dt} = \frac{K_bA_b}{L_b} \quad (T_b - T_{bo}) \quad \dots \quad (9)$$

where the expression on the left side of the equation is the cooling rate of the bellows and the expression on the right the rate of conduction to the outer wall of the bellows.

The energy conducted to the outer wall of the bellows is transferred to the propellant by convection.

$$\frac{K_b A_b}{L_b} (T_b - T_{bo}) = h A_b (T_{bo} - T_g) ... (10)$$

NO	EER57	16068	8Y	WT	PAGE	10
REV	NC					
DATE	1-19-72]

Equation 10 can be solved for T_{bo} and the result substituted in equation o . The resulting expression may be written

$$dt = \frac{1 + \frac{Kb}{hLb}}{\frac{KbAb}{LbMbCb}} \frac{dTb}{Tb - Tg}$$

an expression which can be integrated if Tb and t are considered as the only variables. Actually, conductivity, specific heat, and the film coefficient vary with temperature, but not sufficiently to invalidate the result. Integration gives

$$t = \frac{\frac{K_b}{1 + \frac{h L_b}{h L_b}}}{\frac{K_b A_b}{L_b M_b C_b}} \qquad ln \frac{(Tb - Tg)t = o}{(Tb - Tg)t = t} \qquad (11)$$

Figure 10 is a plot of Tb vs t obtained from equation 11 for the oxygen MFC. Values used for the constants are listed below.

Kb =
$$1.16 \times 10^{-4}$$
 BTU

Sec - in - °F

Lb = 7.85×10^{-3} In

Cb = $.076$ BTU

1b - °F

Ab = 38.2 In^2 (Bellows area and mass were calculated neglecting the end fittings)

Mb = $.174 \text{ lbs}$

h = $.34 \times 10^{-3}$ BTU

Sec - in - °F

Belleville Spring - An analogous expression to equation 11 for the relationship between belleville spring temperature Ts and time t is as follows:

$$t = \frac{\int + \frac{Ks}{hLs}}{\frac{Ks}{Ls} \frac{As}{As}} \ln \frac{(Ts - Tg) t}{(Ts - Tg) t} = 0$$
(12)

١	NO	EER	716068	8Y	WT	PAGE
	REV LTR	NC				
	DATE	1-19-72				

The equation was derived in the same manner as the equation for the bellows. The spring was considered symmetrical to a plane passing through its center (perpendicular to its axis) with the length of heat transfer equal to 1/4 its thickness and a heat transfer area equal to its surface area, or

 $L_s \Rightarrow .0188$

 $A_s = 18 in^2$

 $M_s = .196 \text{ in}^2$

Film coefficient, conductivity and specific heat was assumed to be the same as for the bellows.

Figure 9 includes a plot of the belleville spring temperature vs. time obtained from Equation 12.

The temperature of the bellows and the belleville spring at any time t was used to calculate a regulated outlet pressure for that same time. The technique used was to calculate (1) the amount that the helium gas charge pressure decreases (assuming that the helium gas temperature closely follows the bellows wall temperature) as a result of its temperature decrease from its initial temperature to its temperature at time t and (2) the amount that the belleville spring force increases ΔF_{S} ; as a result of its temperature decrease from its initial temperature to its temperature at time t. The regulated pressure at time t was taken to be its initial regulated pressure (360 psia) plus the belleville spring effect (ΔF_s /AB) less the pressure change of the helium charge. (This calculation did not include a term for the pressure drop through the unit. It did use a bellows charge pressure, 112 psia at 100 degrees F, which is correct for a MFC without the pressure drop effect (See paragraph 3.2). Results of the calculation are plotted in Figure 10. It shows that the MFC, when subjected to a step temperature change of 310 degrees F, regulates within three psi of the correct pressure setting for the new propellant temperature within approximately two seconds. It is interesting to note from Figure 11 that after 2 seconds time the temperature of both the bellows (-162 degrees F) and the belleville spring (-67 degrees F) are considerably greater than the propellant temperature (-210 degrees F) and yet the regulation pressure is within 3 psi of the correct regulation pressure. This apparent paradox is explained by noting that the effect of a bellows temperature error is opposite from the effect of a belleville spring temperature error; i.e. a bellows temperature higher than the propellant causes a high regulation pressure whereas a high belleville spring temperature causes a low regulation pressure.

4.0 <u>DESIGN</u>

The Mass Flow Controller design is shown in Figures 11 and 12. Its primary elements are a shutoff valve incorporating a housing, a shutoff valve, a pressure balanced throttling device, consisting of a stationary cylinder and a rotating cage, a hermetically sealed bellows assembly containing a helium gas charge, and a negative rate belleville spring. These elements are pictured in Drawing 5716187 and Drawing 5716068, reduced size copies of which are included as Figures 1 land 12. These elements are discussed in some detail below.

4.1 Housing

The MFC is designed for an operating pressure of 2000 psia inlet and 360 psia outlet (at 100 degrees F). Proof pressures are 3000 psia and 540 psia respectively. The housing is structurally sound for outlet pressures up to 2000 psig but such pressures would damage the bellows. Safety factors at the flanges for inlet and outlet pressures of 3000 and 2000 psig respectively are shown on Figure 13.

4.2 Shutoff Valve

The shutoff valve is a piston operated type controlled by a separate solenoid pilot valve. The poppet, which is clamped to the piston at its inner periphery, has some self-alignment capability at its seating surface, which projects beyond the skirt of the piston and seats on a raised, flat-lapped annulus on the cylinder. In the closed position the poppet is pressure loaded in contact with the seat.

The piston is normally spring loaded to the closed position. Pressure at the inlet communicates with the piston chamber via the solenoid pilot valve. When the solenoid pilot valve is energized, the piston chamber is connected to the outlet port of the MFC. This causes the piston chamber to bleed down until the inlet pressure opens the piston. The piston is prevented from slamming opening by the built-in snubber action as the piston approaches its open position stop.

The piston is guided by a CRESstem which moves in a filled Teflon bearing. Its peripheral seal consists of two step-cut piston rings of a filled Teflon material backed up by a CRES expander ring.

4.3 Cylinder and Cage

The throttling element consists of a stationary cylinder and a rotating cage, each with six peripheral slots. Throttling occurs as the slots in the cage rotate out of alignment with those in the cylinder.

	NO	EER5716068	BY	WT	PAGE _	13
	REV LTR	NC				
	DATE	1-19-72				

4.3 (continued)

There are six slots in the cylinder and six matching slots in the cage. Four of the slots are 1/8-inch wide and two are 1/4-inch wide. The orientation is such that the four narrow slots close simultaneously when the two wide slots are in their mid position. There is .0025 radial clearance (nominal) between the two parts when installed. Twenty-three degrees rotation from the closed position is required to fully open all slots. The flow area versus rotation is shown on Figure 14.

4.4 Bellows Assembly

The bellows used in the MFC was an off-the-shelf item. It has 7-1/2 active convolutions and was obtained by machining an existing 14 convolution bellows obtained from Robertshaw Controls Company, Knoxville, Tennessee. This bellows, Robertshaw P/N A2000A08, is a single-ply, hydrostatically formed, seamless, 18-8 CRES bellows with the following specifications:

OD: 2.00

ID: 1.34 inches

Wall thickness: . 0157 in.

Length per active corrugation: .110 in.

Spring rate per active corrugation: 4000 lb/in

Maximum stroke per action corrugation: .023 in.

Effective area: 2.22 in.

Maximum pressure rating: 395 psi differential

Bellows Spring Rate

The spring rate of the bellows is made up of a mechanical portion, or that due to the spring rate of the 7-1/2 active convolutions, and a pneumatic portion. The pneumatic spring rate results from the fact that the bellows cannot be deflected without compressing or expanding the internal charge. If the internal charge follows an isothermal process during deflection, the pneumatic spring rate may be calculated as follows:

Differentiating the perfect gas equation for an isothermal process (pV = constant),

$$P_{b} \frac{dV}{dL} + V \frac{dP_{b}}{dL} = 0$$

$$Since dV = {}^{A}_{B} dL \text{ and } dP = \frac{dF}{A_{B}}$$

$$\frac{dF}{dL} = -A_{B} \frac{P}{V}$$
(13)

NO	EER5716	068	вү	WT	PAGE	14
REV LTR	NC					
DATE	1-19-72					

The mechanical spring rate is approximately 535 lb/inch at room temperature and decreases with increasing temperature at a rate of approximately 2% (10.7 lbs/inch) per hundred degree change. The pneumatic rate is directly proportional to the internal pressure and consequently increases with increasing temperature. The bellows assemblies were charged with helium to 148.7 psia (bellows assembly at midstroke, 100 degree F temperature) for the oxygen MFC and 133.6 psia for the hydrogen MFC. (See Paragraph 3.2) The spring rate variation with temperature is shown below for the bellows used in the oxygen MFC.

Temperature	Mechanical Spring Rate	Pneumatic Spring Rate	Assembly Spring Rate
Degrees F	lb/inch	lb/inch	lb/inch
100	532	490	1022
-210	565	219	784

4.5 Belleville Spring

The spring loads, as described in the preceding paragraph, were found to be:

 $F = 246.3 \times 2.22 = 546 \text{ lbs.}$ for the oxygen unit and $F = 261.4 \times 2.22 = 580 \text{ lbs.}$ for the hydrogen unit

Approximately 20 lbs of each of the above loads is obtained from the compression of the bellows. The remainder is the calculated load of the belleville at its midstroke position.

The belleville spring operates in the negative spring rate regime throughout the operating stroke (.036 inches) of the linkage. The spring rate of the belleville spring was designed to be near the spring rate of the bellows assembly. If the two were equal (but of opposite sign) the net spring rate would be zero. A zero spring rate system would permit the throttling device to take whatever restrictive position required by changing pressure and/or temperature of the propellant without change of outlet pressure. For stability reasons, however, it is desirable that the net spring rate remain positive.

4.6 Solenoid Pilot Valve

The Solenoid Pilot Valve is a two-position, three-way direct operating valve purchased from Circle Seal Corporation, Part No. SV 30 A 32 P 4 T, cleaned for oxygen service.

	NO	EER5716	068	8Y	WT	PAGE_	15
	REV LTR	NC					
	DATE	1-19-72					

5.0 TEST PROGRAM

The test program was originally planned to include component tests, prototype tests, Acceptance Tests and Design Verification Tests. It was necessary to expand this to include additional tests, termed "Pre Production Tests" because of unanticipated problems requiring (1) redesign of the cage and cylinder and (2) modifying the bellows charge.

5. 1 Component Testing

At the beginning of the program, certain components were recognized as being critical to the success of the all-mechanical Mass Flow Controller. These were (1) the cage and cylinder assembly (2) the charged bellows and (3) the belleville spring. Development tests were planned for these components to verify their performance as components before assembly into a complete MFC.

5. 1. 1 Cage and Cylinder Assembly

A prototype case and cylinder were machined from 17-4 barstock in accordance with Parker Drawings 5716069 and 5716070, both to Revision A. These components were assembled and tested in a test fixture.

When pressure was applied, a high separating force was developed. This was determined to be caused by inadequate venting of the space between the cage and cylinder. The venting area was increased by slotting the end plate of the cage and chamfering its forward end. This eliminated the high separating force.

Torque testing of the cylinder and cage was conducted at various pressures with an orifice in the outlet line downstream of the fixture of a size which will pass rated flow at approximately 300 psi in the test fixture. Torque readings were obtained using hand held torque wrench and also using an electrically driven torque meter. Results of the test using the torque meter are included as Figure 15. The torques obtained indicate an opening torque on the cage, that is, the fluid tends to align the slot in the cage with the slot in the cylinder.

An effort was made to eliminate or reduce the magnitude of the torque by the following three methods.

- (1) Shaping of the leading edge of the slot in the cage.
- (2) Attaching a fence to the cage at two of the slots which protruded into the slot of the cylinder. The arrangement is shown in Figure 16. The fences produce an unbalanced pressure area which result in a closing torque when the slot in the cage is in the near closed position.

NO	EER571	6068	BY	WT	PAGE	16
REV LTR	NC					
DATE	1-19-72					

(3) Attaching a shroud to the cage which directs the flow from the slots in a longitudinal direction. The shroud is pictured in Figure 17. Various positions of the shroud were tried relative to the slots in the cage.

The various devices tried in an effort to reduce the torque altered the shape of the torque-displacement curve but none showed a consistent improvement of the total torque range over the working angle of the assembly.

When parts became available to complete the assembly of a MFC, the prototype cylinder and cage in its unmodified form was used in the assembly. The assembly was tested over an inlet pressure range of 400-1000 psig and performed without any problem traceable to a torque on the cage. Further torque tests of the cylinder and cage were discontinued.

5. 1. 2 Prototype Bellows

A prototype bellows assembly was fabricated and filled with helium to a pressure of 112 psia at midstroke and 100 degrees F temperature. (The pressure was calculated to be the required charge pressure for an oxygen MFC without a flow sensitivity correction). The bellows was stroked using a spring tester and a force deflection-curve obtained both for increasing load and for decreasing load. From this curve the following data was obtained.

Force at midstroke: 225 lbs.

Spring rate of filled bellows, 75 degrees F = 835

Hysteresis: negligible

The prototype bellows was used in the prototype MFC assembly. The performance of this unit is shown in Figure 19.

5.2 Prototype MFC Testing

The first MFC was assembled using the prototype cage and cylinder, the prototype bellows assembly and the prototype belleville spring. It was tested in the test setup shown in Figure 19.

Pressure regulation performance of this unit is shown in Figure 19. Analysis of this data resulted in the following conclusions:

- (1) Scatter of data at a particular flow rate is approximately 12 psi (-6 psi).
- (2) Decreasing the flow rate by changing the downstream orifice from .687 diameter to .624 diameter causes an upward shift in control pressure of approximately 20 psi at 0 degrees F.

NO	EER5716	068	BY	WT	PAGE	_
REV LTR	NC					
DATE	1-19-72					٦

(3) The slope of the pressure vs. temperature curve at constant flow rate is less steep than the target curve. The target curve shown is obtained from the oxygen curve of Figure 3 less (a) 14.7 psi to convert it to a sea level gage pressure reading) and (b) the velocity head in psi for rated flow in the outlet line where outlet pressure is measured.

The prototype MFC was cycled 1000 times at room temperatures using a solenoid pilot valve. Inlet pressure was 400 psia. Following the cycle test the unit was disassembled and inspected. No damage was detected as a result of the cycle test.

5.3 Pre Production Testing

Analysis of the results of testing the prototype components and the prototype MFC assembly led to certain design changes. The bellows assembly charge pressure was increased to increase the slope of the pressure regulation curve and the cage and cylinder were altered for increased strength and improved performance.

The cage wall thickness was increased to strengthen it where the prototype cage had proved weak. The journal of the bearing was increased in section to reduce the deflection resulting from the linkage loads.

The radial clearance between the cage and cylinder was decreased and the length of the slots were decreased to reduce the fluid torque effects and consequently improve precision. The cage and cylinder were made in a four-slot and six-slot version. Comparative tests showed the six slot version markedly superior. All testing of the four-slot version was discontinued and six-slot cages were ordered for all production units.

At this time it was decided that remaining performance testing would be conducted over a 500-700 psi inlet pressure range rather than 400-2000 psi design range. The limited inlet pressure range avoids the inlet pressures which cause a still unexplained rise in outlet pressure of approximately 20 psi. The inlet pressure range of 500 to 700 psig is consistent with use of a roughing regulator upstream of the MFC.

The body which had been used on the prototype MFC was modified by adding a second outlet port. This was accomplished by drilling a hole in the body downstream of the cylinder and cage assembly, tapping a 1-inch pipe thread and installing an AN816-16 nipple. The body was used in a complete assembly using a six slot cage and cylinder configuration. The original outlet port was capped

NO	EER571	6068	вү	WT	PAGE_	18
REV LTR	NC			T		
DATE	1-19-72					

and the unit placed in the test setup with the downstream system, including the orifice, connected to the new outlet port. In this configuration the flow passes from the cylinder and cage to the outlet, bypassing the belleville spring and bellows. Outlet pressure was modified at the port in the original outlet flange which opens to the region of the bellows. The bellows assembly used was charged to 135 psia at 100 degrees F, midstroke position.

The modified assembly was tested with orifices of .687 diameter and .562 diameter installed in the outlet. The resulting pressure regulator curves are shown in Figure 20. The curve for the .687 diameter orifice shows the outlet pressure to be approximately 42 psi higher at 0° F than when tested in the conventional manner. This increase results from (1) elimination of the closing force on the belleville spring and (2) measurement of the pressure at a location which is at the same pressure level as the bellows. The tests also show an upward shift in outlet pressure of approximately 9 psi (at 0° F) when the orifice in the outlet is changed from .687 to .562 diameter. This is a smaller shift than occurs when testing the unit in the conventional manner but is greater than anticipated.

Analysis of the test data resulted in the revised bellows charge levels described in paragraph 3.2. A bellows charged to the new level was assembled in a MFC using an unmodified body. The pressure regulation curves resulting are shown in Figure 21 for an orifice size of .687 and .624 diameter. A point on the rated flow performance curve is obtained where the test points taken for a .687 diameter orifice cross the rated flow line for that orifice. A second point on the rated flow performance curve is obtained where the test points for the .624 diameter orifice cross the rated flow line for that orifice. A line joining these two points is the rated flow performance curve. This curve shows the correct slope for an oxygen MFC and the correct pressure level.

The best transient temperature test occurred during test of this unit. The inlet temperature was suddenly lowe red by approximately 300°F. The recorder trace obtained is reproduced as Figure 22. It shows inlet temperature, outlet temperature and outlet pressure vs. time. The test was conducted with a .624 diameter orifice in the outlet line and an inlet pressure of approximately 600 psig. The trace shows the inlet temperature changing more rapidly than the temperature measured at the bellows which is to be expected since there is some warming of the gas as it passes through the MFC. The outlet pressure responds more rapidly than either temperature which indicates that the charged bellows responds more rapidly than the thermocouples used in the test.

The data from Figure 22 is reproduced on a larger scale in Figure 23. Plotted also in Figure 23 is the transient curve prepared from calculations for a step temperature change. (See paragraph 3.3 and Figure 10.)

The test curve covers a greater pressure range since it is a test with a .624 diameter orifice in the outlet line (hence the flow rate increases as the temperature decreases) rather than with constant rated flow throughout the temperature range. The test curve shows the outlet pressure to change more slowly than the calculated curve. Part of the difference is explained by the fact that (1) a true step temperature change was not obtained in the test and (2) some warming of the flow occurs between the inlet and the bellows which was not accounted for in the calculations.

NO.	EER5716068	BY _	WT	PAGE
REV LTR	NC			
DATE	1-19-72			

An interesting recorder trace obtained with the preproduction unit by amplifying the outlet pressure signal. This trace is reproduced as Figure 24. It shows very clearly the variation in outlet pressure as the temperature varies. It also shows the outlet pressure responds more rapidly than does the thermocouple used to measure the temperature.

5.4 Acceptance Tests

Four MFC units were assembled in accordance with the Manufacturing Operations Routing for Part No. 5716068, a copy of which is included in the appendix. For each bellows assembly and each belleville spring used, a load deflection curve was obtained by use of a spring tester. These curves are included in the appendix. The curves show a belleville negative spring rate somewhat greater in magnitude than the bellows assembly positive spring rate. This results in a slightly negative spring rate of the MFC which is undesirable for stability. Instability did not prove to be a problem however during testing at limited inlet pressures (500-700 psig).

All production MFC units, adaptors and solenoid pilot valves were tested in accordance with PTS5716068. Copies of these documents are included in the appendix. Results of these tests are summarized below. Copies of actual data sheets are included in the appendix.

NO. E	ER5716068	 BY	WT	PAGE	20
REV LTR	NC				
DATE	1-19-72				

5. 4. l Leakage

Leakages recorded for the four production units are summarized in Table 1. External leakage occurred at the joint when the cap attaches to the body which sees inlet pressure, and at the joint where the housing attaches to the body, which sees outlet pressure. The seals used consist of a single piece Teflon jacket with an internal CRES expander spring and are standard parts obtained from Raco. Surfaces in contact with the seals have finishes and dimensions in accordance with the seal manufacturer's recommendations. Total external leakage at the limited inlet pressure is less than 10 sccm.

Internal leakage occurred at the poppet seat (which may have been augmented by leakage past two Raco seals which are potential parallel leakage within two light bands and with a finish of four micro inch, except for one oxygen MFC, S/N 02. This unit leaked excessively.

Another leakage recorded on the data sheets but not listed in Table 1 is the piston leakage. This is the leakage past the piston ring and occurs only when the MFC unit is open. This leakage passes through the solenoid pilot valve and into the MFC outlet, bypassing the throttling device. It produces no detectable effect on the performance of the MFC.

5. 4. 2 Pressure Response

A recorder trace obtained during a pressure response test is shown as Figure 25. Four inputs were monitored:

- (a) Solenoid voltage
- (b) Inlet pressure
- (c) Outlet pressure
- (d) Pressure in the shutoff piston chamber

5. 4. 2. 1 Opening Response

When the solenoid pilot valve is energized it shuts off the fluid communication path from the MFC inlet to the shutoff valve piston chamber and opens a communication path from the piston chamber to the MFC outlet. The pressure in the chamber then blows down until the shutoff piston begins to move. Once the piston begins to move, the downstream face of the piston, unpressurized when closed, becomes pressurized. The increased area exposed to pressure produces sufficient force on the piston to open it fully without further flow of gas from the piston chamber.

1	NO	EER57	16068	вү	WT	PAGE	21
	REV LTR	NC	-				
	DATE	1-19-72					

The opening time can be considered to consist of four intervals:

- (1) Solenoid Response Time the time required for the two-position solenoid pilot valve to shift position after energization. (60 milliseconds)
- (2) Blowdown Time the time required to depressurize the piston chamber to the pressure at which the piston can begin to move. (60 milliseconds)
- (3) Piston Travel Time the time required for the piston to travel sufficiently to pass rated flow. (20 milliseconds)
- (4) Controller Reaction Time the time for the throttling element, which is initially fully open, to overshoot, recover, and achieve regulation. (20 milliseconds)

The times shown in parentheses are the times taken from the recorder traces of Figure 25.

5.4.2.2 Closing Response

When the solenoid pilot valve is de-energized it shuts off the fluid communication path between the piston chamber and the MFC outlet port and opens a path from the MFC inlet to the piston chamber. The pressure in the piston chamber then rises to near inlet pressure and is closed by the piston return spring. When the piston approaches the seat the pressure drop across the piston produces an additional closing force.

The closing time can be considered to consist of 4 intervals.

- (1) Solenoid Response Time: the time required for the two-position solenoid pilot valve to shift position after de-energization.
 (5 milliseconds)
- (2) Pressurization Time: the time required for the chamber to pressurize to the point when the spring can initiate closing. (25 milliseconds)
- (3) Spring Closure Time: the time required for the spring to return the piston from its fully open position to the point when the pressure drop across the piston aids closure. (115 milliseconds)
- (4) Pressure Assisted Closure Time: the time required for the piston to move the final distance under the influence of the pressure drop across the piston and, to a lesser extent, the spring force. (10 milliseconds)

These times shown in parentheses are the times taken from the recorder traces of Figure 25.

	DATE	1-19-72		·			

5.4.3 Control Pressure with Varying Inlet Pressure

Pressure regulation performance was obtained over an inlet pressure range up to 1000 psig with the temperature essentially constant. A typical trace obtained from one of the four units (an oxygen MFC, Serial No. 02) is included as Figure 26. This curve shows that the MFC controls outlet pressure high by as much as 20 psi when the inlet pressure is between 400 and 500 psig for both increasing and decreasing inlet pressure. The reason for this pressure rise was not established conclusively but is suspected to be associated with torqueon the cage. The outlet pressure is low also during increasing inlet; pressure between 700 and 900 psig and during decreasing inlet pressure between 950 and 700 psig although the effect is not so great as at the low inlet pressures.

5. 4. 4 Control Pressure with Varying Temperature

Pressure regulation performance was obtained throughout the temperature range with the inlet pressure in the 500-760 psig range. Each unit was tested without thermal conditioning using a .687 diameter orifice in the outlet. An orifice of .624 inch diameter was substituted prior to the test runs in which thermal conditioning was accomplished. A curve plotted for one of the four units (an oxygen MFC, Serial No. 02) is shown on Figure 27. Similar curves for the remaining three units are included in the appendix. The curves show that the units were not adjusted as precisely as was the preproduction unit. (See Figure 21.) The slope of the constant flow curve does not match the target slope as well as did the preproduction unit.

5. 4. 5 Thermal Response

Thermal response was conducted on each unit and the results tabulated in Table 2. This shows the magnitude of the inlet temperature change resulting from a sudden opening of the liquid nitrogen supply and the time required for the outlet pressure to reach the new equilibrium pressure.

5.5 Design Verification Testing

One of the four units (a hydrogen MFC, Serial No. 01) was subjected to Design Verification Testing in accordance with DVT5716068, a copy of which is included in the appendix. Test results are summarized in Table 3. Copies of actual data sheets are included in the appendix.

5. 5. 1 Endurance Test

The unit was cycled with the solenoid pilot valve at an inlet pressure of 400 psig. A sufficiently small orifice was installed in the outlet to cause the throttling element to reach its fully restricted position each time the solenoid valve opened. Ten thousand cycles were imposed. Poppet leakage following the cycle test was approximately the same as before the test. The piston leakage increased but not sufficient to affect performance

NO	EER5716	068	BY	WT	PAGE _	23
REV LTR	NC					
DATE	1-19-72					

5. 5. 2 Pressure Drop Test

The pressure drop test was conducted at an outlet pressure well below the set pressure to assure that the throttling element was in its fully open position. At 100 °F (outlet pressure of 360 psia) the test data indicates a pressure drop of 60 psi which exceeds the 40 psi design point. The excess pressure drop resulted from the changes to the cage and cylinder following the prototype tests, which decreased the open flow area. The pressure drop of the unit is adequate for the revised inlet pressure range (500 - 700 psig), which requires a pressure drop less than 155 psi at full flow.

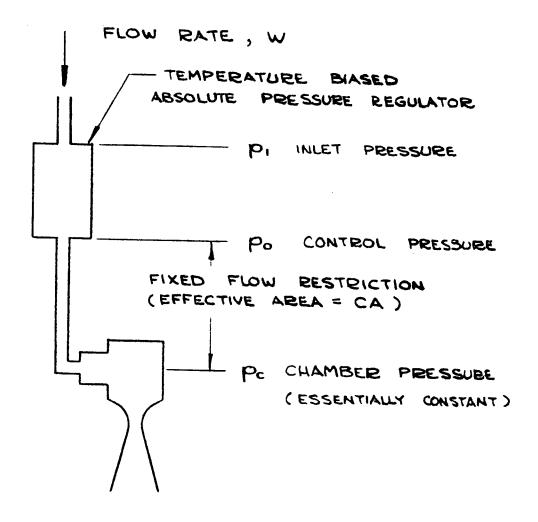

5.6 Helium Test

One of the two hydrogen units (Serial No. 02) was tested for stability using helium as the flowing medium. The test setup was identical to that shown on Figure 18 except that a "six pack" of helium bottles manifolded together was connected to the MFC inlet in place of the gaseous nitrogen supply. No thermal conditioning was employed but the spherical pressure vessel was utilized (by opening ball valve B2) to lengthen the time of the test run. This was necessary since the opening from the manifolded six pack was too small to meet the flow demand of the MFC. An orifice of .687 inch diameter was installed in the outlet for this test. The inlet pressure was approximately 600 psig. No audible instability was detected with helium as the test medium nor did the outlet pressure as monitored by the recorder indicate an instability. The length of the test run obtainable by this test method is too limited to establish conclusively that the MFC is stable with helium flowing.

REV LTR	NC					
DATE	1-19-72					

6.0 CONCLUSIONS AND RECOMMENDATIONS

- 6.1 The all mechanical mass flow controller can control outlet pressure within ± 1 percent over the entire temperature range (250 ° F to + 100 °F) provided the inlet pressure range is limited to 500-700 psig. Further development is recommended to increase the inlet pressure range without adversely affecting the control pressure band. The element in the MFC which requires improvement is the throttling device (the cylinder and cage).
- 6.2 The errors in mass flow control and mixture ratio resulting from a pressure control error of ± 1 percent were determined by analytical techniques. It is recommended that these errors be determined also during test firing of a rocket engine with the propellants supplied through two all mechanical MFC units.
- The error in mass flow and mixture ratio resulting from an error in control pressure of ± 1% is shown over the entire temperature range in Figure 28. The curve was calculated on the basis of a pressure drop through the fixed restriction of 60 psi (at 100 °F). For a pressure drop of 120 psi the errors in mass flow and mixture ratios are less. These are plotted in Figure 29. It is recommended that the pressure drop allowable through the fixed restriction be reviewed to ascertain whether it can be increased and how much.
- one MFC unit supplies a cluster of rocket engines. The flow sensitivity can be considerably reduced, by redesigning so that the flow does not pass through the belleville spring. Additional improvement can be achieved by reducing the pressure drop between the throttling element and the outlet port. It is recommended that further work be performed to determine how much improvement is feasible.

SYSTEMS DIVISION PARKER MANNIFIN

NO <u>Р</u>	TS571618	8Y	WT P	AGEl
REV LTR	NC			
DATE	10-18-71			

1.0 SCOPE

This document specifies the test procedure for the Mass Flow Controller (MFC) Solenoid Pilot Valve and Adapters supplied to NASA Houston for controlling the flow of gaseous hydrogen and gaseous oxygen propellants, PN 5716187.

2.0 TEST REQUIREMENTS

- 2.1 <u>Test Facilities</u> All testing shall be conducted at the Systems Division, Parker Hannifin Corporation, Irvine California Facility.
- 2.2 <u>Test Results</u> Complete test results data shall be recorded for each acceptance test.
- 2.3 <u>Environmental</u> Unless otherwise specified all testing shall be conducted within the following environmental conditions:
 - a. Temperature: $75^{\circ} \pm 20^{\circ}F$
 - b. Relative Humidity: 90 percent or less
 - c. Barometric Pressure: Local Atmosphere
- 2.4 Test Media The test media used for acceptance testing shall be nitorgen in accordance with MIL-P-27401.
- 2.5 <u>Tolerances</u> Unless otherwise specified, the following tolerances apply to the application of test requirements and the recording of data:
 - a. Temperature: ± 3°F
 - b. Barometric Pressure: ± 5 percent
 - c. Pressure: ± 1 percent
 - d. Flow Rate: ± 2 percent
 - e. Leakage Rate: ± 3 percent

SYSTEMS DIVISION PARKER (HANNIFIN

NO	P188 <u>71</u>	6187	BY	WT	PAGE	
RLV t,TR	NC					
DATE	10-18-71					

3.0 <u>DETAILED TEST PROCEDURES</u>

- 3.1 Solenoid Valve
- 3.1.1 Proof Pressure
- 3.1.1.1 Setup Connect pressure source to Ports A, B and C to permit pressurizing all three ports simultaneously.
 - 3.1.1.2 Procedure Apply 3000 psig for 5 minutes.
 - 3.1.2 External Leakage
 - 3.1.2.1 Setup Same as proof pressure test.
- 3.1.2.2 <u>Procedure</u> Apply 2000 psi to ports and immerse valve in freon or alcohol past the flange where solenoid mounts. Observe for bubbles. There shall be no bubbles during 2 minute test.
 - 3.1.3 Internal Leakage
- 3.1.3.1 <u>Setup</u> Connect pressure source to NO PortA and connect tube to Port B. Cap Port C. Immerse tube in liquid.
- 3.1.3.2 <u>Procedure</u> Apply 2000 psi to Port A and observe for bubbles. Record number of bubbles during 2 minute test.

Remove tube from liquid and energize valve with 28 volts DC. Immerse tube and observe for bubbles. Record number of bubbles during 2 minute test.

- 3.1.4 Actuation
- 3.1.4.1 <u>Setup</u> Connect pressure source to NO Port A and connect gauge to Port C. Leave Port B open.
- 3.1.4.2 <u>Procedure</u> Apply 2000 psi to Port A and energize solenoid with 28 volts DC. De-energize solenoid. Repeat 5 times observing gauge. Valve must open and close promptly as signified by pressure at the gauge.

SYSTEMS DIVISION PARKER (2) HANNIFIN

NO	PTS5716	187	BY	<u>VT</u>	AGE3
REV LTR	NC				
DATE	10-18-71				

- 3.2 <u>5716154 Inlet Adapter Proof Test</u>
- 3.2.1 Setup Install Inlet Adapter in Fixture No. S65-0-1802.
- 3.2.2 Procedure Apply 3000 psi for 5 minutes.
- 3.3 5716155 Outlet Adapter Proof Test
- 3.3.1 Setup Install Outlet Adapter in Fixture No. S65-0-1802.
- 3.3.2 Procedure Apply 2000 psig for 5 minutes.
- 3.4 5716068-101 and -102 Mass Flow Controller Assy

Test per PTS5716068 Acceptance Test Procedure.

3.0 DETAILED TEST PROCEDURES

- 3.1 Proof Pressure and External Leakage
- 3.1.1 Setup The test setup shall be as shown in Figure 1.
- 3.1.2 Procedure

Inlet - Open shutoff valves V_1 and V_3 and close V_2 . Immerse unit and apply 3000 psig with regulator valve for two minutes. Reduce pressure to 2000 psig and observe for bubbles. There shall be no bubbles in a two minute test.

Outlet - Close shutoff valve V_1 and V_3 and open valve V_2 . Apply 525 psig to inlet port for two minutes. Reduce pressure to 400 psig and observe for bubbles. There shall be no bubbles in a two minute test.

- 3.2 Internal Leakage
- 3.2.1 Setup Use setup shown in Figure 1 except attach flow meters to outlet of shutoff valves V_2 and V_3 suitable for measuring internal leakage.

SYSTEMS DIVISION PARKER (A HANNIFIN

NO _	PTS5716	068	BY	<u>W T</u> P	AGE3
REV	1 (5.1)				
DAT	E 10-8-71				

3.2.2 Procedure

 $\frac{\rm Poppet}{\rm Poppet}$ - Open shutoff valves $\rm V_1$ and $\rm V_3$ and close $\rm V_2$. Using regulator valve apply pressure to inlet port of 400, 1000 and 2000 psig. Record leakage from $\rm V_3$.

 $\frac{\text{Piston Seal}}{\text{Using regulator valve apply pressure to inlet port of 50, 100, 200 and 400 psig.}}$ Using regulator valve apply pressure to inlet port of 50, 100, 200 and 400 psig. Record leakage from V_2 .

3.3 Response & Regulation

3.3.1 Setup - Use setup shown in Figure 2. For tests conducted without adding LN_2 , use orifice diameter of .687 inch. For tests conducted with LN_2 use orifice diameter of .624 inch. Record p_1 , p_2 , p_3 , T_1 , T_2 , and voltage at solenoid.

3.3.2 Ambient Temperature Tests (.687 inch orifice)

- 3.3.2.1 Using dome loader D_1 , establish the pressure which results in 550 ± 50 psig at P_1 when the MFC is open and flowing. Open MFC shutoff poppet by closing switch. Use a recorder speed sufficient to obtain response of unit. Close MFC by opening switch.
- 3.3.2.2 Open MFC by closing switch with inlet pressure of 350 ± 50 psig. Increase inlet pressure to 1000 psig and lower to 350 psig, obtaining a trace of outlet pressure as inlet pressure varies.
 - 3.3.2.3 Repeat 3.3.2.1 with inlet pressure set for 1000 ± 50 psig.

3.3.3 <u>Cold Test</u> (.624 inch orifice)

3.3.3.1 Using dome loader D_1 establish the pressure which results in 550 ± 50 psig when the MFC is open and with LN_2 injected in quantity sufficient to produce an outlet temperature of -210°F or lower. Using dome loader D_2 , establish a pressure on the LN_2 container required to flow LN_2 at the required rate when ball valve B_2 is opened.

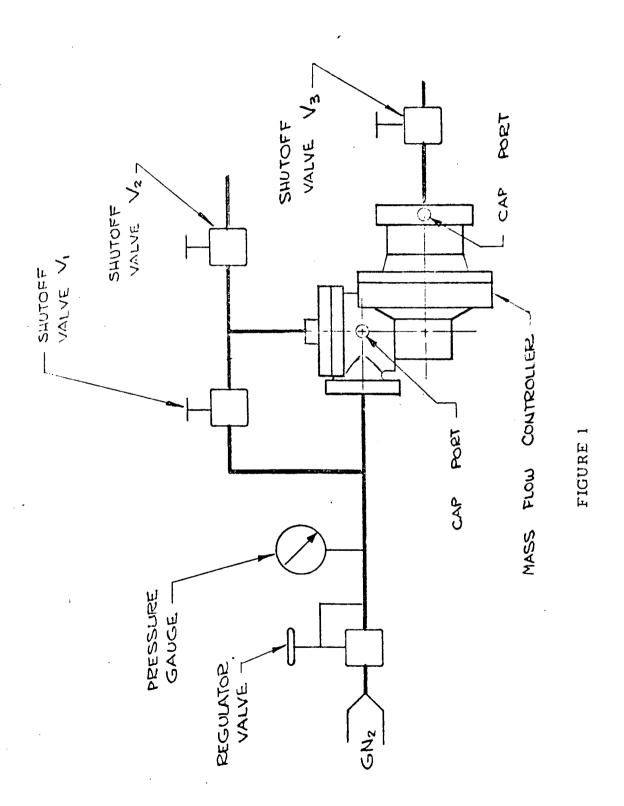

SYSTEMS DIVISION PARKER (() HANNIFIN

NO _F	PTS571606	<u> </u>	8Y	W. J	P#GE	<u> </u>
REV LTR	NC			T		
DATE	10-8-71					

- 3.3.3.2 Close switch and open ball valve B₂ simultaneously. Obtain a trace of outlet pressure as the temperature drops to -210°F.
- 3.3.3.3 Close B_2 (and increase pressure of dome loader D_1 if required to maintain inlet pressure to MFC) and obtain trace of outlet pressure as temperature warms to ambient.
 - 3.3.3.4 Repeat 3.3.3.1 3.3.3.3 with inlet pressure of 1000 ± 50 psig.
 - 3.3.4 During response and regulation test
 - a. Note any region of instability.
 - b. Observe for evidence of external leakage when MFC is cold.

1.0 SCOPE

This document specifies the test procedure to be followed for design verification testing of two mass flow controller assemblies.

PN 5716068-101 Hydrogen Mass Flow Controller

5716068-102 Oxygen Mass Flow Controller

2.0 TEST REQUIREMENTS

- 2.1 <u>Test Facilities</u> All testing shall be conducted at the Systems Division, Parker Hannifin Corporation, Irvine California Facility.
- 2.2 <u>Test Results</u> Complete test results data shall be recorded for each design verification test.
- 2.3 Environmental Unless otherwise specified, all testing shall be conducted within the following environmental conditions:
 - a. Temperature: $75^{\circ} \pm 20^{\circ}F$
 - b. Relative Humidity: 90 percent or less
 - c. Barometric Pressure: Local Atmosphere
- 2.4 <u>Test Media</u> The test media used for design verification testing shall be nitrogen in accordance with MIL-P-27401.
- 2.5 <u>Tolerances</u> Unless otherwise specified, the following tolerances apply to the application of the test requirements and the recording of data.
 - a. Temperature: ± 3°F
 - b. Barometric Pressure: ± 5 percent
 - c. Pressure: ± 1 percent
 - d. Flow Rate: ± 2 percent
 - e. Leakage Rate: ± 3 percent

3.0 DETAILED TEST PROCEDURES

- 3.1 <u>Internal Leakage</u> Conduct internal leakage test per paragraph. 3.2 of PTS5716068.
- 3.2 <u>Response & Regulation</u> Conduct response and regulation test per paragraph 3.3 of PTS5716068.

SYSTEMS DIVISION PARKER (2) HANNIFIN

NO	DVT 571	6068	вү	WT	PAGE _	<u>Z</u>
REV LTR	NC					
DATE	10-8-71					

3.3 Pressure Drop

- 3.3.1 <u>Setup</u> Use setup shown in Figure 2 of PTS5716068. Use .718 dia orifice in outlet line.
- 3.3.2 Procedure Using D1, set inlet pressure of 300 psig. Close switch, initiating flow through MFC. Increase inlet pressure from 300 to 400 psig in 10 psi increments. Record inlet pressure, outlet pressure, outlet temperature, ip at venturi flowmeter.

3.4 Endurance

- 3.4.1 <u>Setup</u> Use setup shown in Figure 2 of PTS5716068. Install .160 dia orifice in outlet line.
- 3.4.2 Procedure Using D_1 establish a pressure of 550 \pm 50 psig at inlet of MFC. Cycle unit 10,000 times by closing and opening switch. At conclusion of test perform ambient temperature tests and internal leakage test (paragraph 3.2 and 3.3.2 of PIS5716068).
